Re: Industrial Automation Engineer (Ignition Development)

Dear Bytecubit Hiring Team,

The work behind this contract is bigger than rebuilding legacy MES screens. The manufacturing client needs a dependable way to preserve live production behavior while moving functionality into Ignition, strengthening SQL and historian context, and creating useful plant-to-cloud data. That combination of continuity, modernization, and data integrity is precisely the operating problem that interests me.

My verified record brings manufacturing systems depth from advanced electronics, high-reliability engineering, 24/7 operations, and a current software-enabled robotics environment. At Vape-Jet, I work across production, quality, engineering issue flow, ERP/Odoo, telemetry, support, and AI-assisted workflows. At Compunetics, I led engineering, manufacturing, quality systems, root cause, process controls, and complex technical programs. At Amazon, I built the operating discipline required to change a live system without losing customer commitments. SQL, Python, workflow design, and data-to-decision mechanisms are part of my technical toolkit.

The alignment is strongest at the system level: industrial operations, manufacturing data workflows, modernization mechanisms, reliability, and cross-functional execution. I do not claim a long production tenure configuring Ignition or administering AVEVA PI. I would enter with that boundary clear and contribute immediately by mapping live behavior, clarifying data context, strengthening release discipline, and translating across manufacturing, engineering, quality, support, and data teams.

Independent candidate vision: <https://russelldudek.github.io/ByteCubit/>

The site demonstrates a Signal Twin Workbench for comparing legacy and target paths, reconciling SQL and historian context, and releasing only when behavior, data, ownership, and rollback evidence are explicit. It also includes a two-page entry plan, candidate thesis brief, and concise role alignment brief.

Bytecubit positions itself around reliable delivery, implementation expertise, data, cloud, custom software, and technical staff augmentation. I would bring the client an operator-technologist who can connect the factory, application, database, and decision layers - and tie each technical change to production, data quality, ownership, and adoption.

My first priorities would be to understand the live application and data estate, identify one bounded function with real operating value, make its dependencies and acceptance conditions explicit, and turn that first release into a reusable pattern for the next function.

Sincerely,

Russell Dudek
